

# Preliminary - Hydrodynamic Simulations of the European Shelf Sea

*Adolf Stips, Elisa Garcia-Gorriz,  
Svetla Miladinova, Rodrigo Perez*  
Joint Research Centre

Environmental Marine Information System  
<http://emis.jrc.ec.europa.eu>

- Why European wide modelling
- Brief introduction to GETM
- Basic features of the setups
- Long term trends of SST
- Compare SST for different Seas
- Results Gulf Lion deep convection
- Conclusions

- Try to achieve harmonized European regional Seas simulations
- Using the same model, similar setups and the same forcing
- To build a database for assessing trends and shifts in the marine system
- To support the development of harmonized indicators for European regional Seas

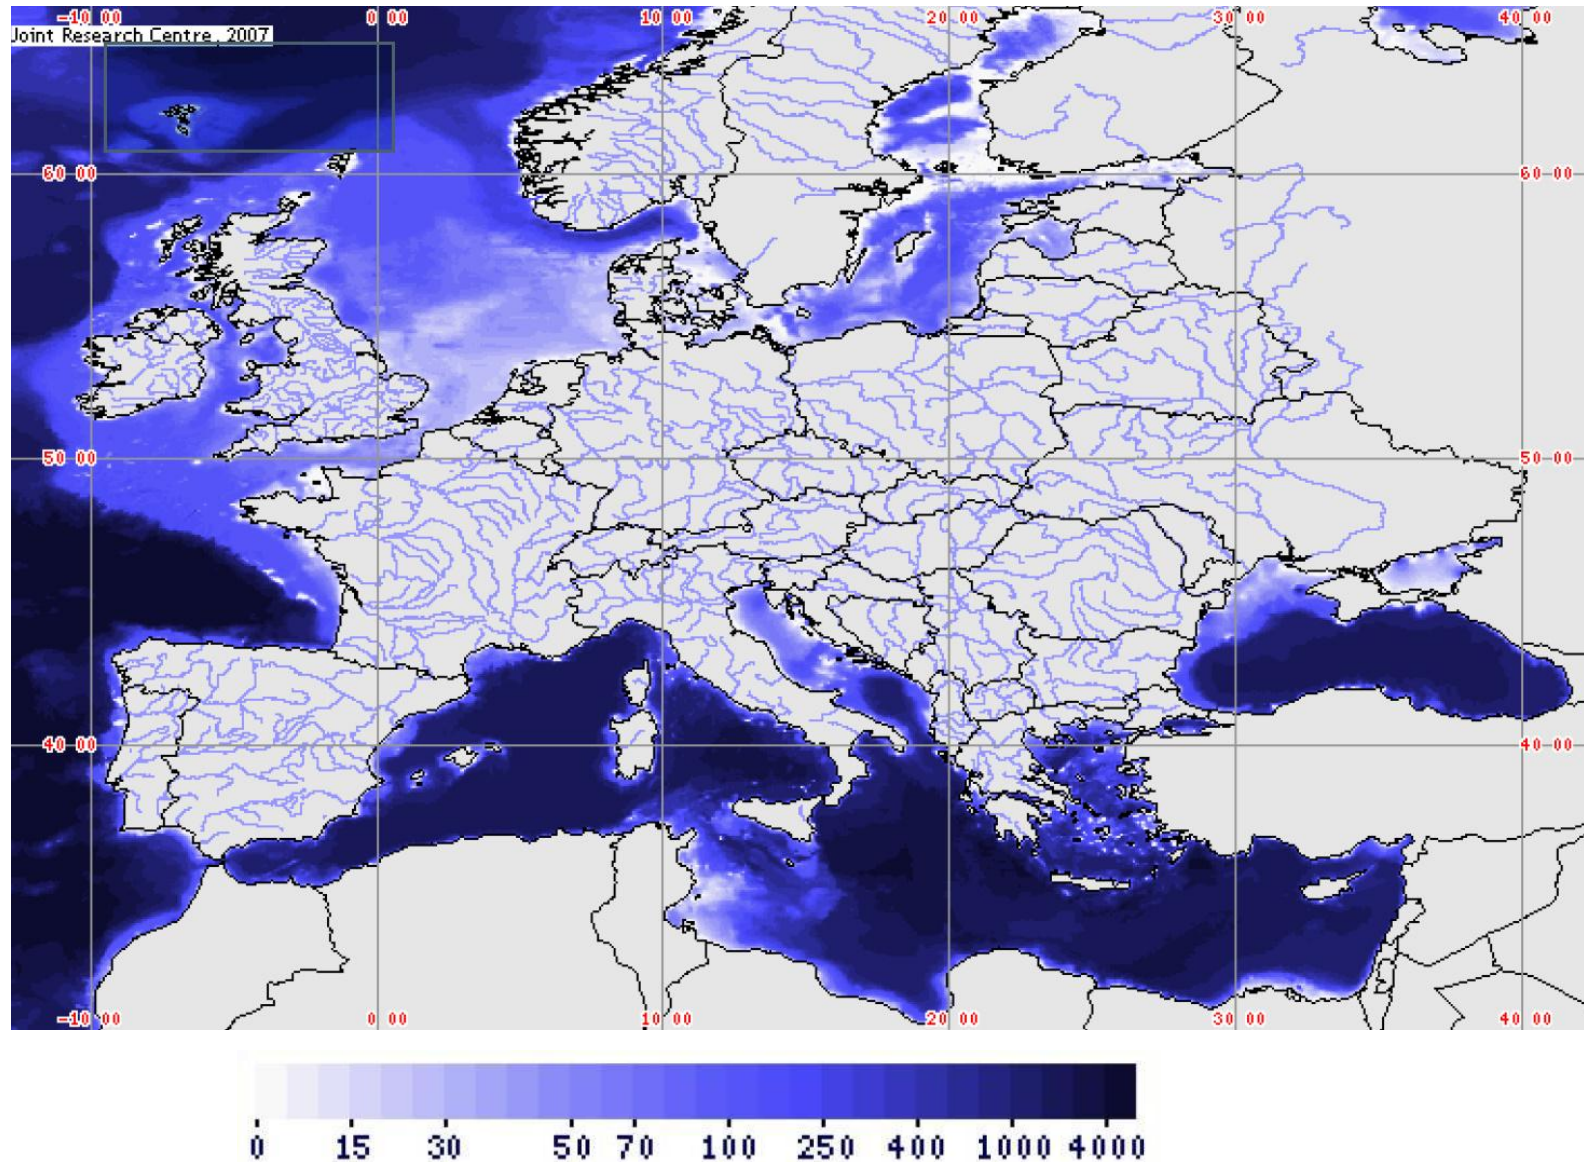

3-D **GETM** model  
(General Estuarine Transport Model, initiated at JRC+, ..  
[www.getm.eu](http://www.getm.eu), [www.gotm.net](http://www.gotm.net))

Very important: Open software (allows principally **reproducible** research)

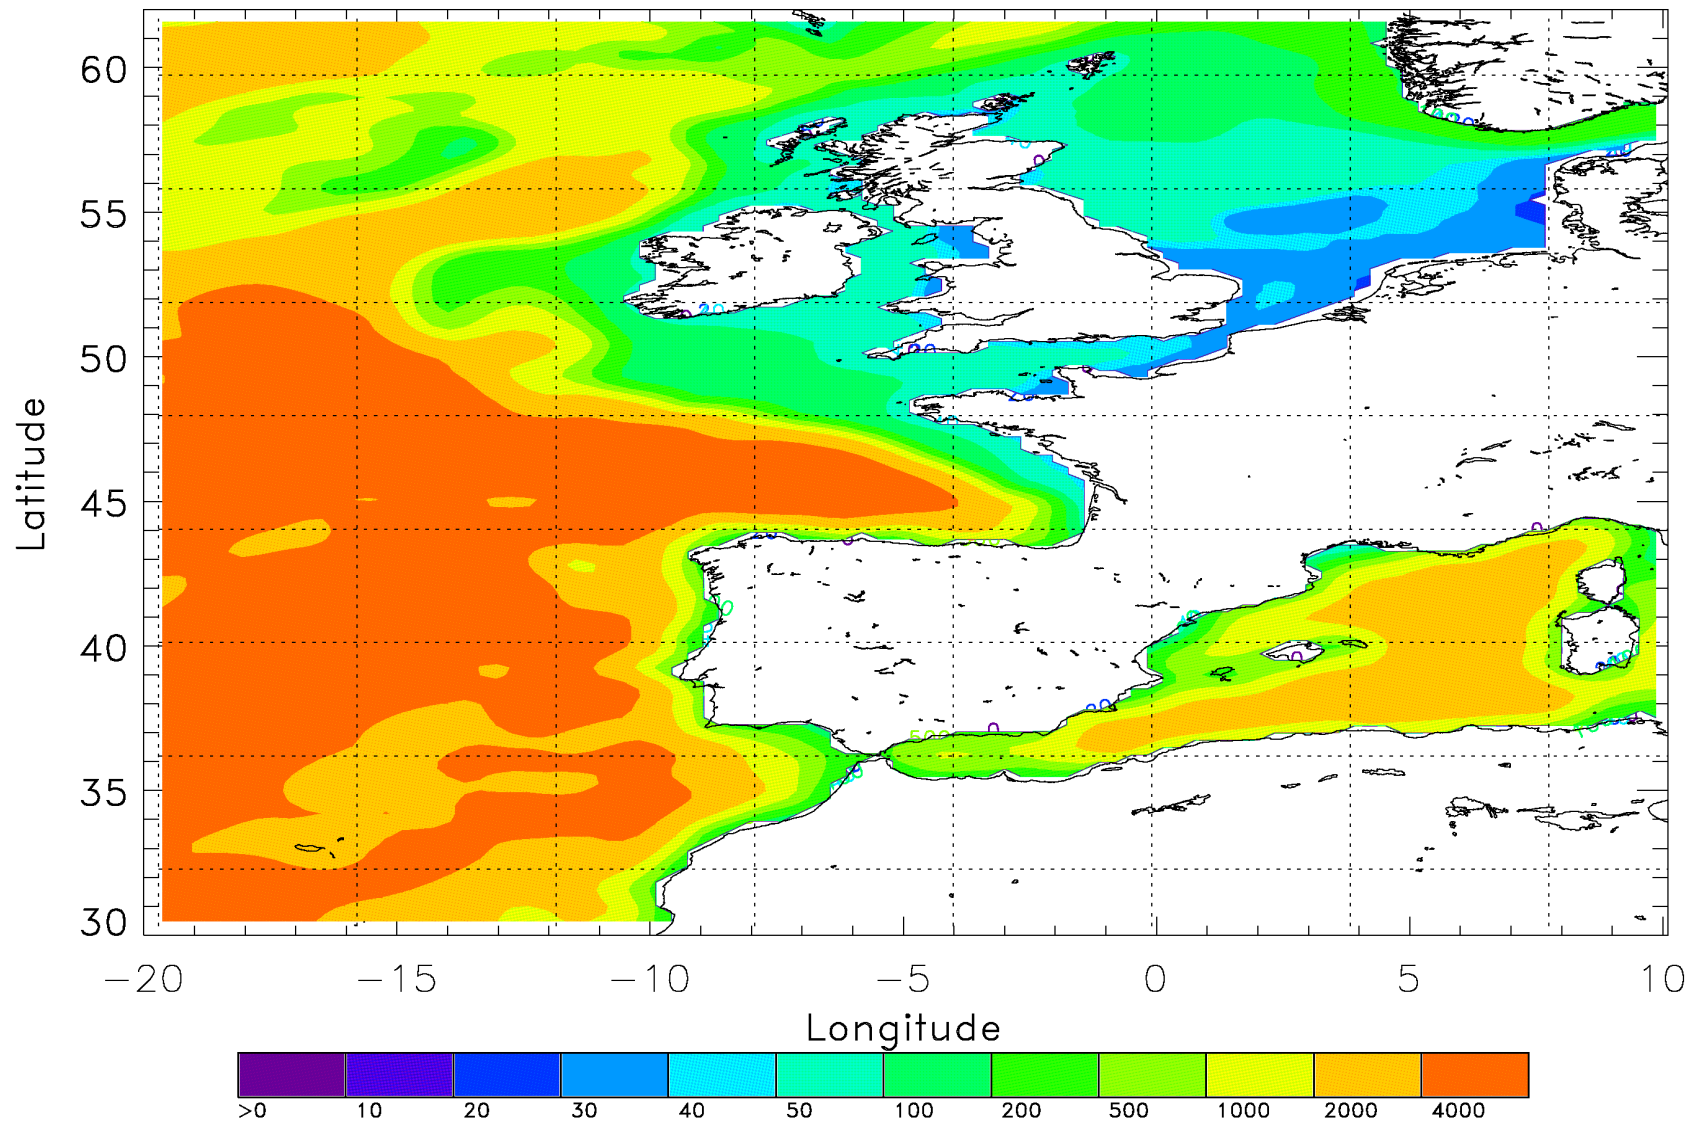

- Turbulence model, TVD advection, terrain following coordinates, int. pres. schemes, bio
- ECMWF meteorological forcing, ERA40, ERA-INTERIM, analysis data (resolution from 125km to about 12km), time coverage changing
- Realistic bathymetry, GEBCO, (0.5x0.5')
- River discharge input, GRDC (**to be improved!**)
- Tide simulation, TOPEX/POSEIDON
- Validation with available satellite and in-situ observations.

- Rather consistent approach for the simulation of European Seas:
  - -Black Sea, 5x5, 2x2, 1x1
  - -North Sea, Baltic Sea, 3x3, 3x2, 2x2, 1x1
  - -Mediterranean Sea: 15x15, 5x5, 2x2, 1x1
  - -Med Sea&Black Sea, 2x2, 1x1
  - -Atlantic Shelf: 15x15, 5x5, 2x2
  - All European regional Seas under construction
- Multiannual simulations: 1960-2009
- Assessment of trends and shifts
- Indicator development, PSA, OXYRISK

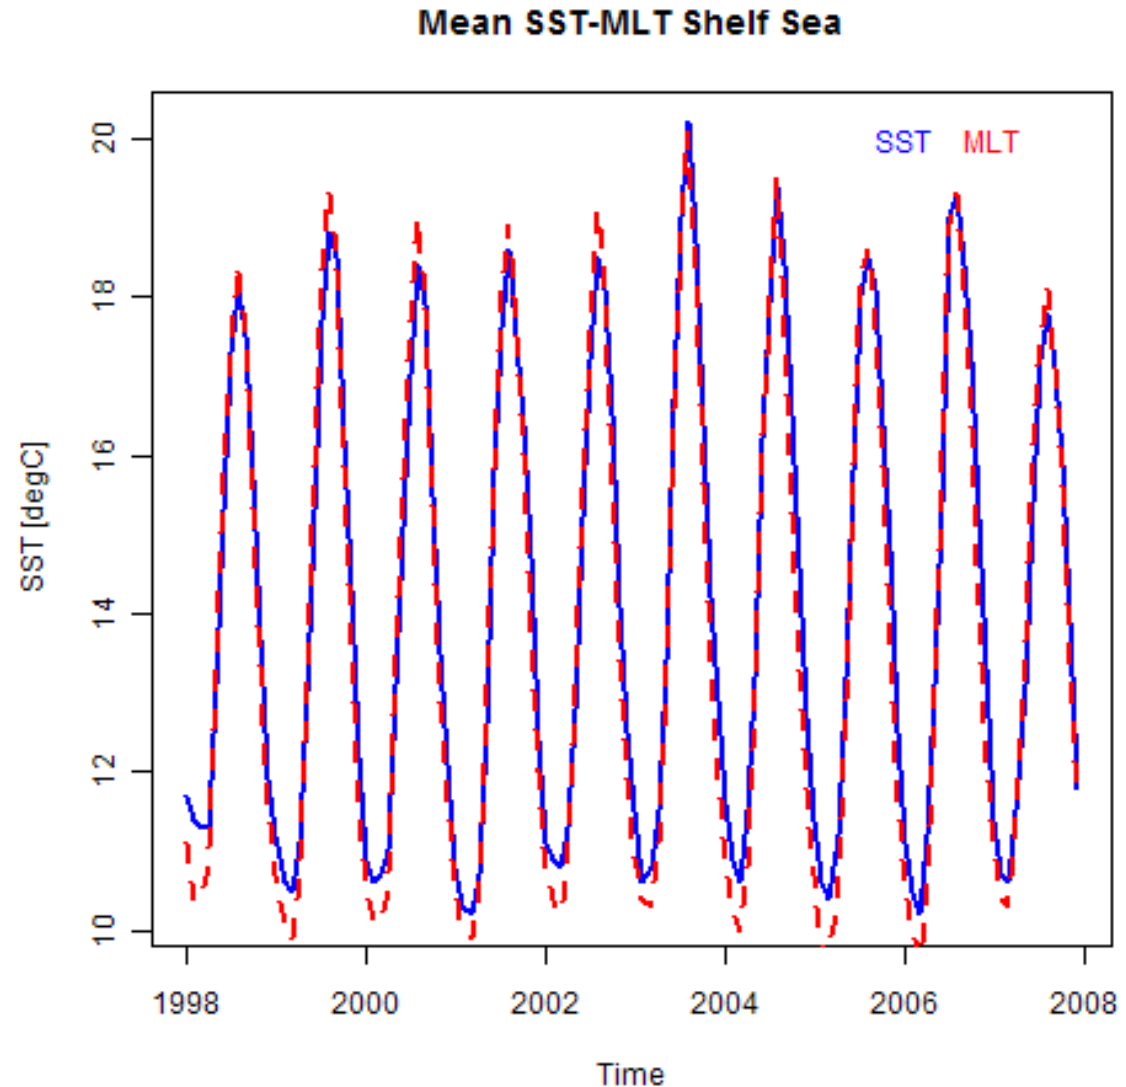

## Atlantic Shelf Bathymetry

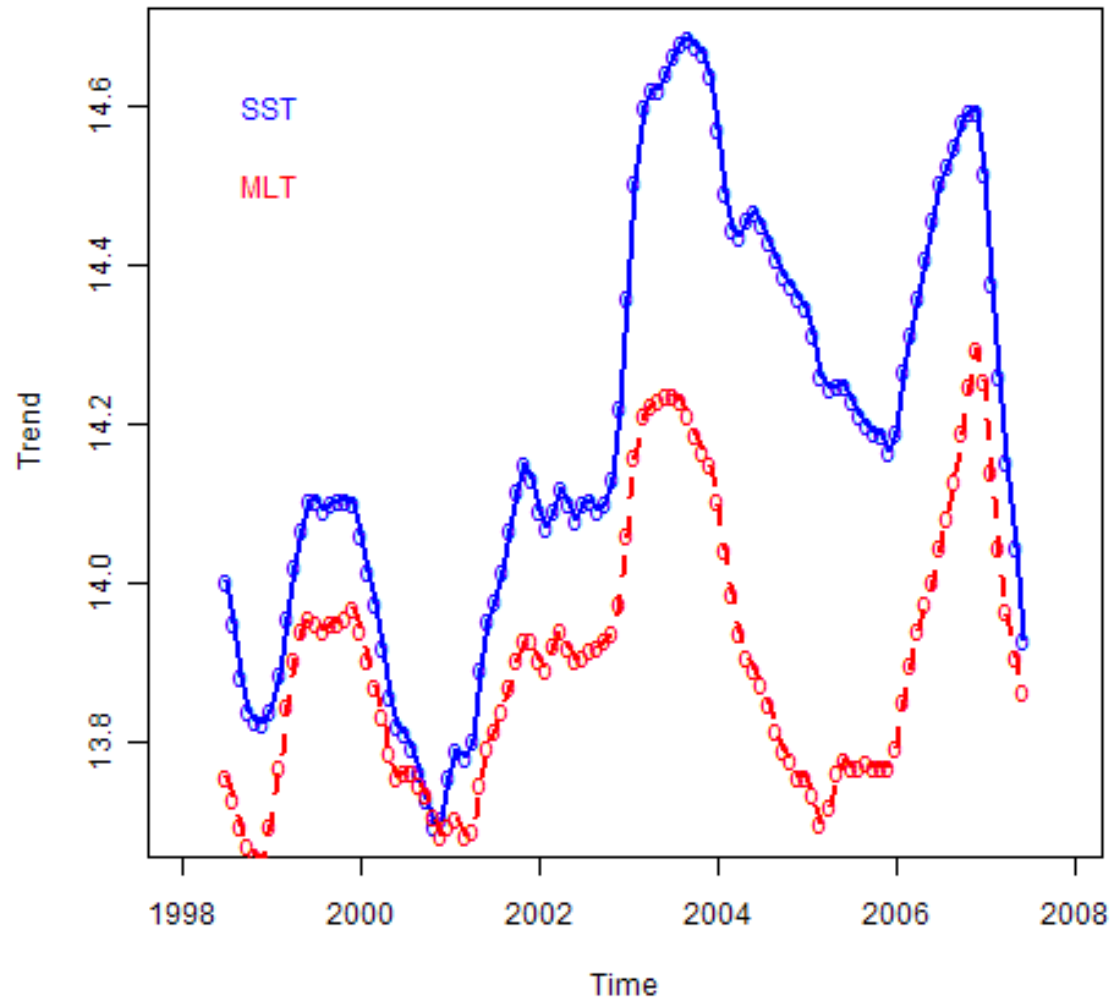

- Satellite SST  
AVHRR
- Seasonal cycle  
rather well  
reproduced
- Winter  
minimum about  
0.4 degC to cold
- Summer first 5  
years 0.3 degC  
to high

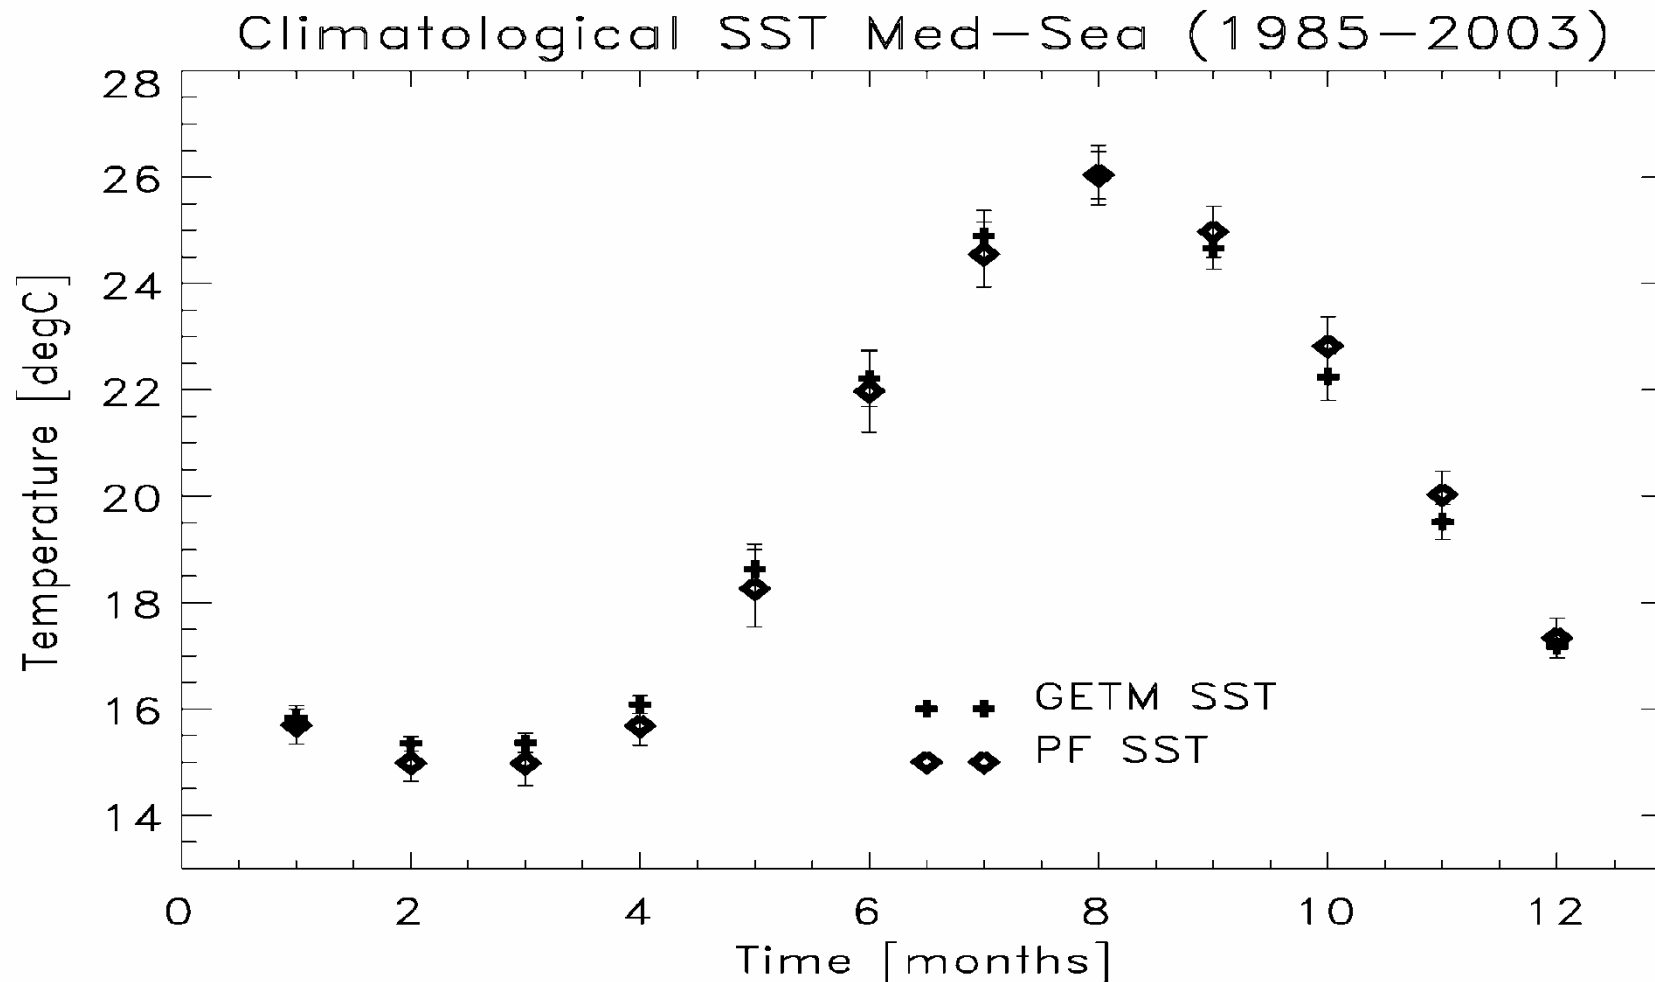

- Low pass filter, removing seasonal signal
- Absolute difference  $\sim 0.3\text{K}$
- Increasing from 2003 (end of ERA40)
- Before ERA-INT, some runs with mixed forcing (visible quality difference!)

Shelf Sea, Trend of SST and MLT

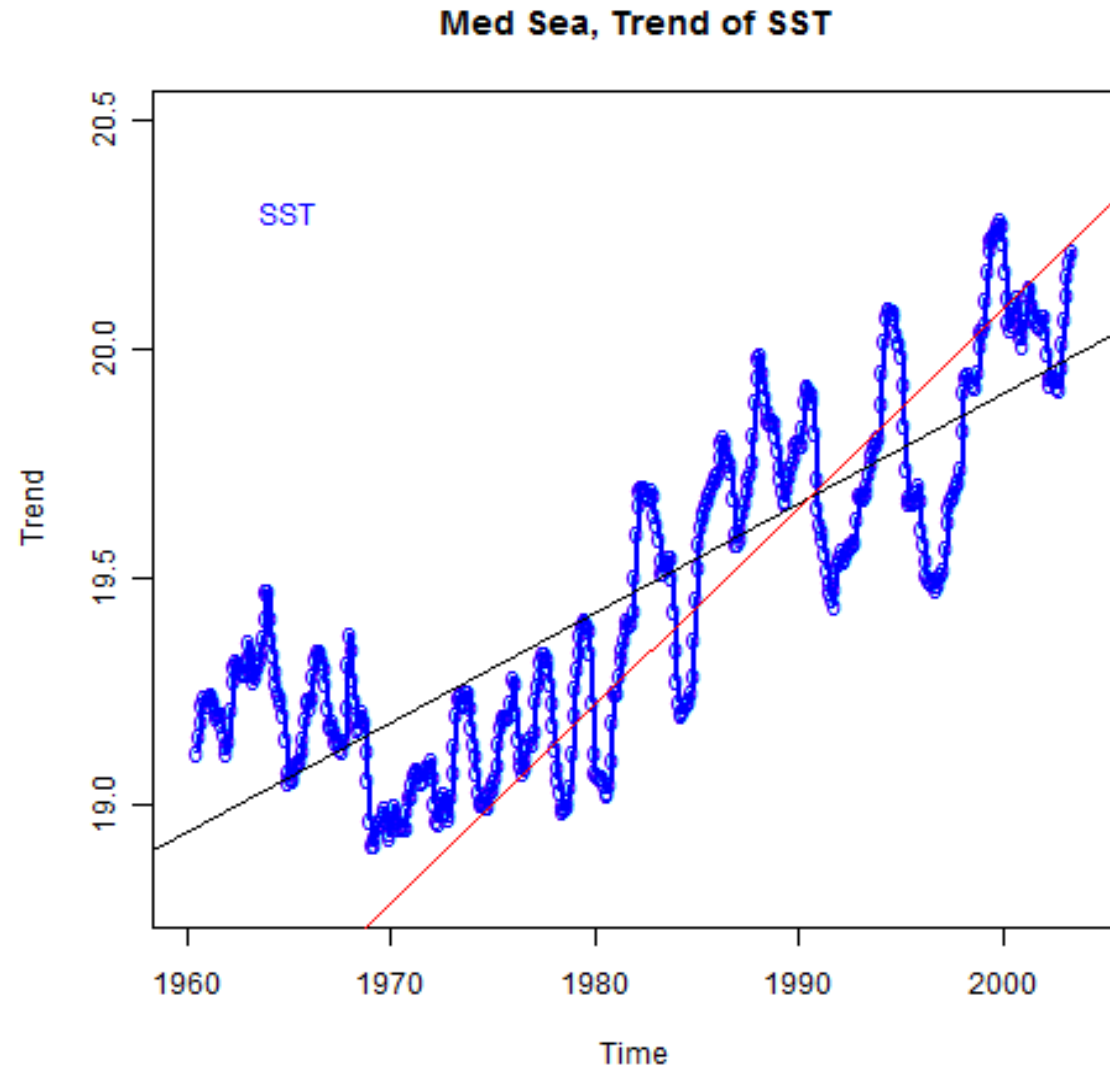

- Problems already with different spatial resolution and temporal coverage of meteo forcing
- But how good is our one flux parametrization fits everything approach?
- Have a look at the different Seas
- First Mediterranean Sea

*Quite okay, non significant differences of < 0.2 degC*

- *Model SST*
- *Forcing with ERA40 only*
- *Warming of about 1.05 K*
- *means 0.024 K/year*  
*(black line)*
- *1960-1980 no trend*
- *Warming begun only*  
*1980*
- *Then it would be 0.043*  
*K/year (red line)*
- *Trend is actually the*  
*same as from satellite*  
*(Nykjaer 2008)*

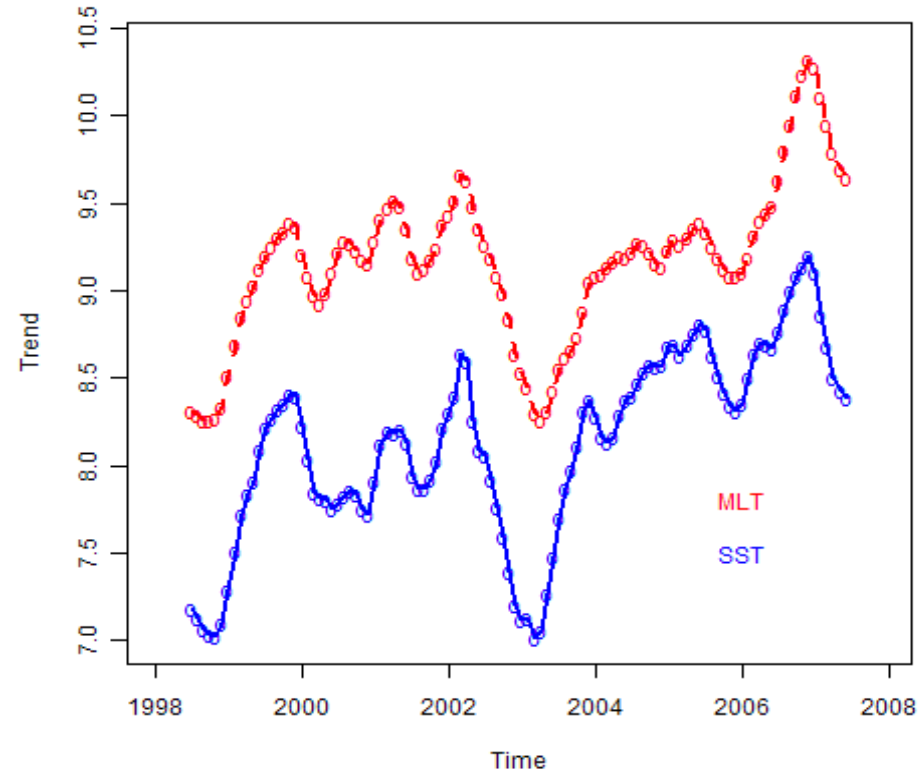

Med Sea, Trend of SST and MLT

Baltic Sea, Trend of SST and MLT

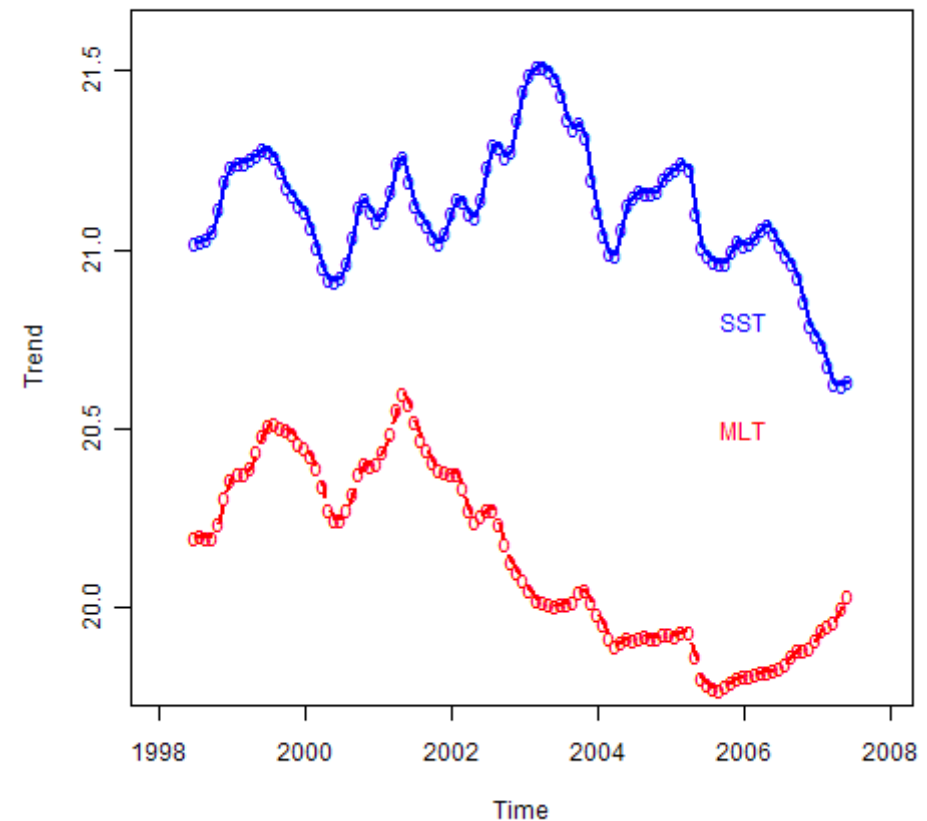

*Low pass filtered SST, simulation Medsea to cold, Baltic Sea to warm (const offset), (Medsea forcing quality degradation)*

**Black Sea, Trend of SST and MLT**

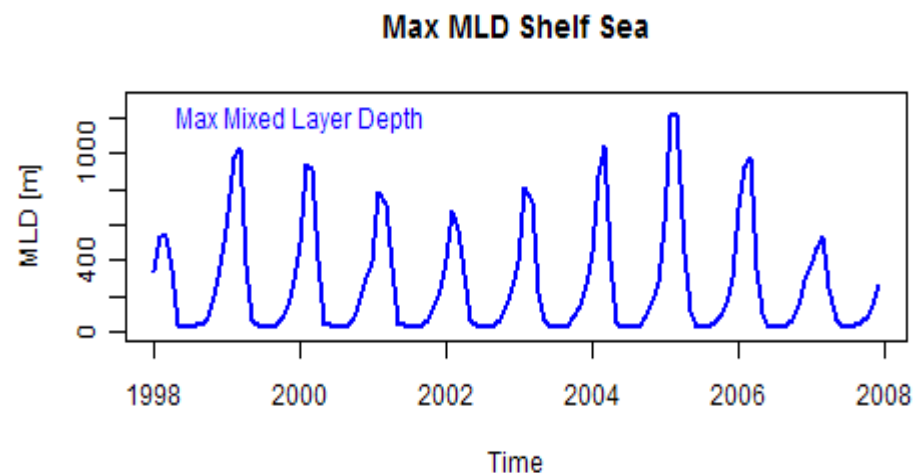

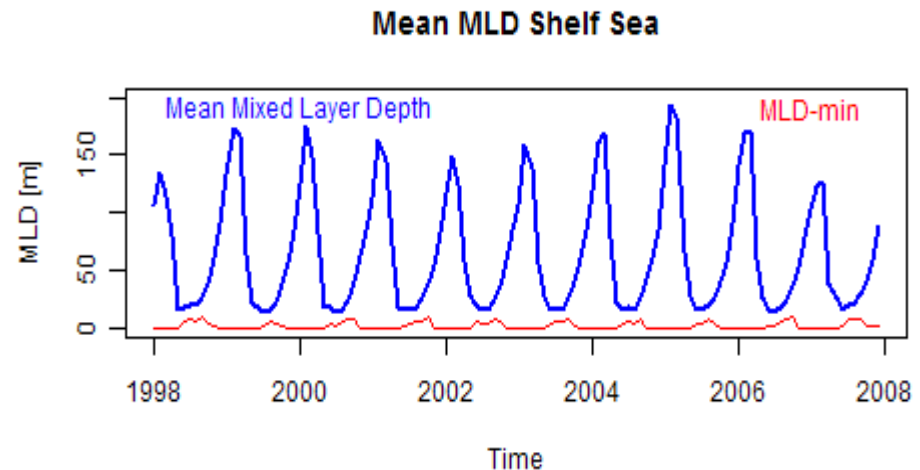

**Eastern Med Sea, Trend of SST and MLT**

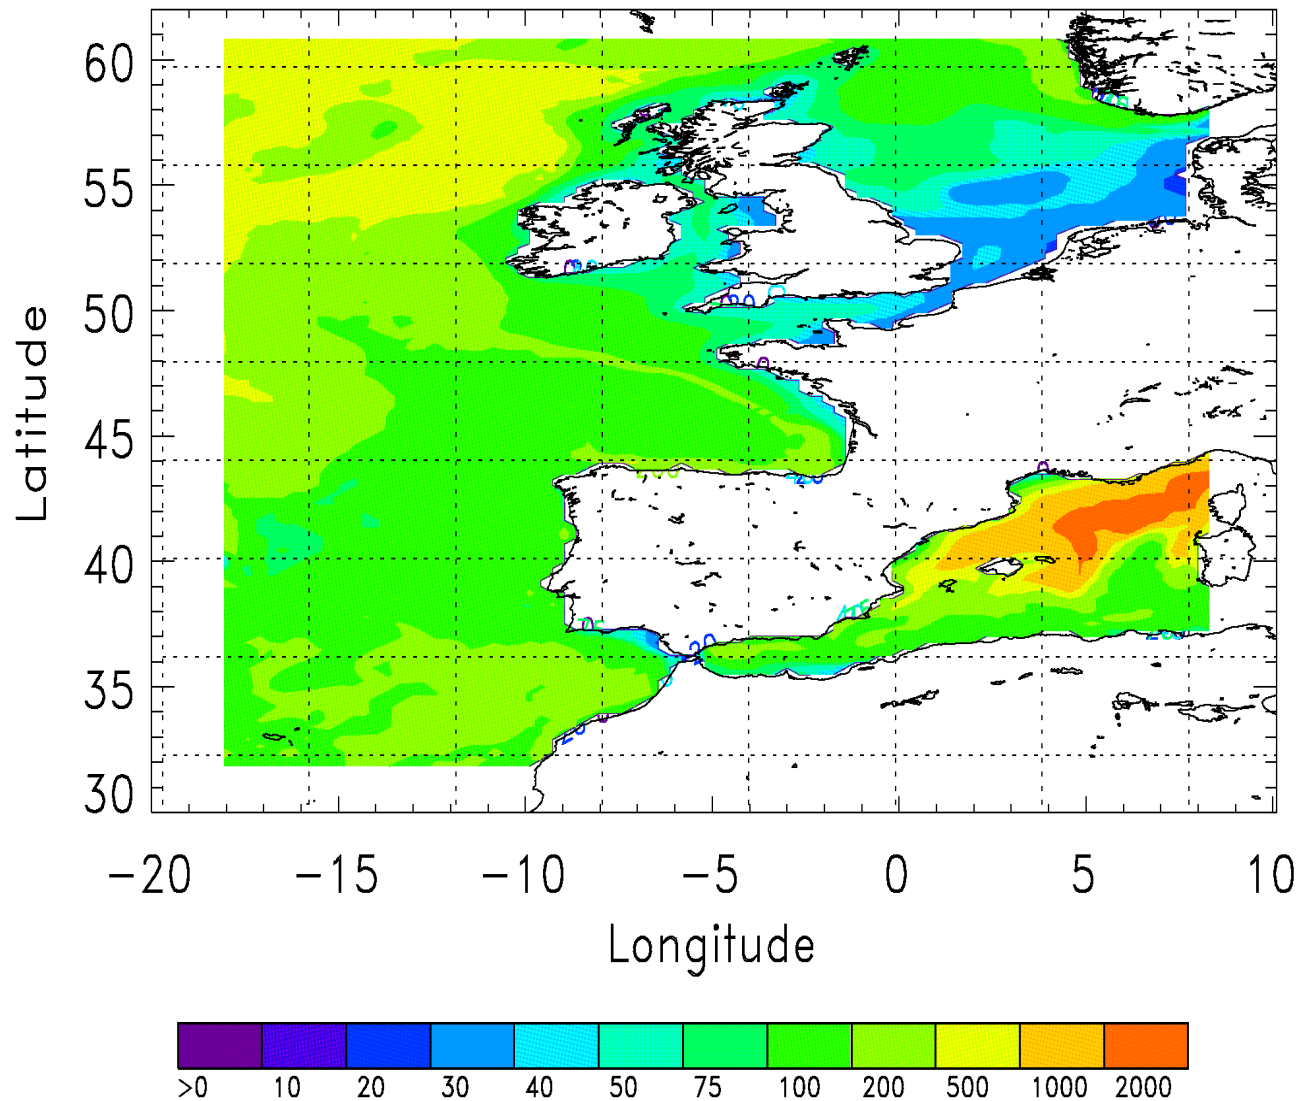

*But even only in the South, Black Sea gets to warm,  
whereas the Eastern Medsea is clearly to cold  
Any good proposals for solving this are welcome!*

- Mean mixed layer depth (MLD) from Shelf Sea run, interannual variability related to atmospheric forcing
- Important for biology, published on EMIS
- Max monthly mean values above 1000m
- Where?

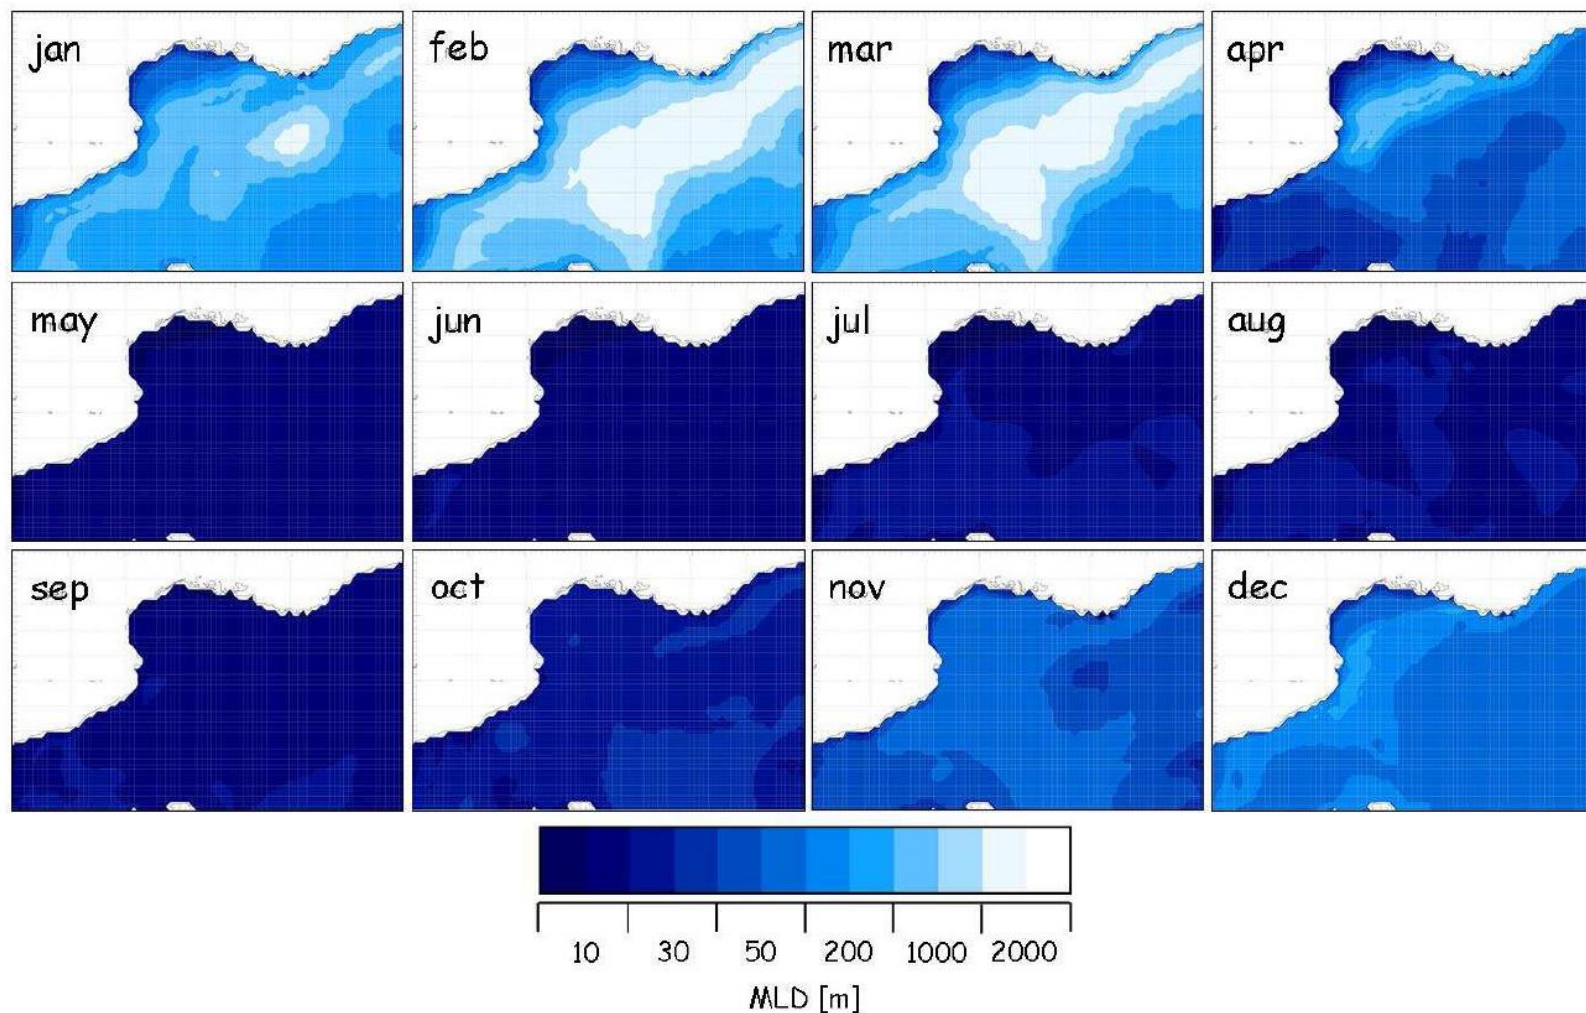

- Deep Convection Gulf of Lions ?
- Herrman and Somot 2008, conclude that with low resolution AF deep convection does not occur, but with HRAF (downscaled ERA40)
- In conclusion, in our runs using ERA40 there should be no deep convection
- Looking on our runs, forced with ERA40 data (e.g. other turbulence model) we get:

## Atlantic Shelf MLD 1999 02

*Example:  
Extended  
region with  
deep  
convection  
during  
February  
1999*

Climatological monthly means, over 10 seasonal cycles (1998 to 2008), of mixed layer depth, *MLD* [m]

- All European regional Seas in one domain?
- How to be done without Supercomputer?

- Harmonized simulation of European Seas
- Obstacles like harmonized forcing
- Air-sea flux parameterizations only conditionally valid for such large areas
- Not shown, just finished an improved run with changed solar radiation (albedo)
- Not touched, boundary condition problematic
- Not touched, steep bathymetry problem
- Remember “reproducible research”
