Wreck removal activities

RAISING THE CONCORDIA

U.S.-based Titan Salvage and Micoperi, an Italy-based salvage company, have been selected to recover the wreck of the Costa Concordia, which ran aground off the Italian island of Giglio in January

SETUP

- 1** Ship stabilized to prevent movement
- 2** Grout laid beneath hull to provide support and help ship pivot
- 3** Subsea platform installed
- 4** Sponsons welded to port side

Length: 950 ft
Beam: 117 ft
Weight: 44,612 MT

REFLOATING

- 1** Concordia is rolled upright along port side
- 2** Inshore sponsons added and holdbacks disconnected
- 3** Concordia should float at a level of 61 ft

Emergency management at sea

The LaMMA Consortium (Tuscany Region / CNR) supports TITAN-Micoperi by a dedicated weather service for the management of removal operations.

Every day a LaMMA's forecaster follows the operation from the Salvage Room at Isola del Giglio.

An integrated sea monitoring system

An important tool for supporting the removal operations is represented by a Remocean X-band RADAR system, that provides information about sea surface currents and waves.

The RADAR is part of a measurement system that includes a wave buoy, a tide gauge, and two meteorological stations.

Finally, a UV-fluorometer for hydrocarbons detection is installed in a desalination plant close to the Giglio port.

X-band RADAR

The X-band RADAR system provides information about the sea state parameters like the wave directional spectra and the current velocities and directions.

The RADAR has been installed at the Giglio port in order to obtain a very high resolution in the coastal zone near the Concordia wreck.

The range of the X-band RADAR is about 3 km.

Currents

UV-fluorometer for Polycyclic Aromatic Hydrocarbons detection in water

Continuous monitoring of hydrocarbons in the desalination plant of 'Acquedotto del Fiora' in the Giglio island

An increase of the hydrocarbon concentration has been observed during the parbuckling operation.

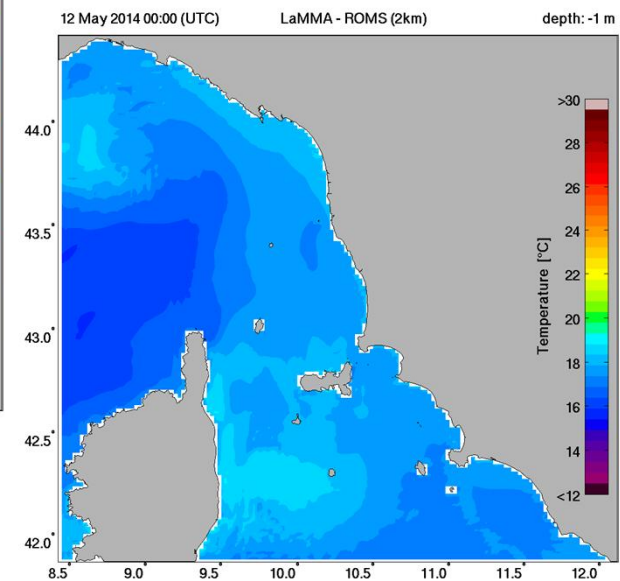

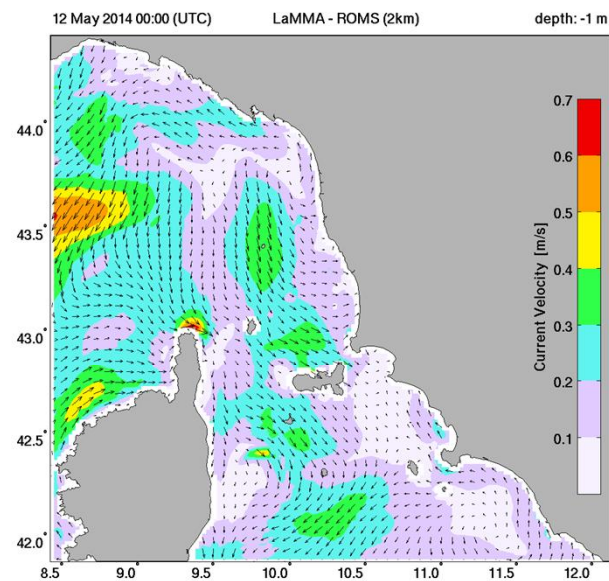

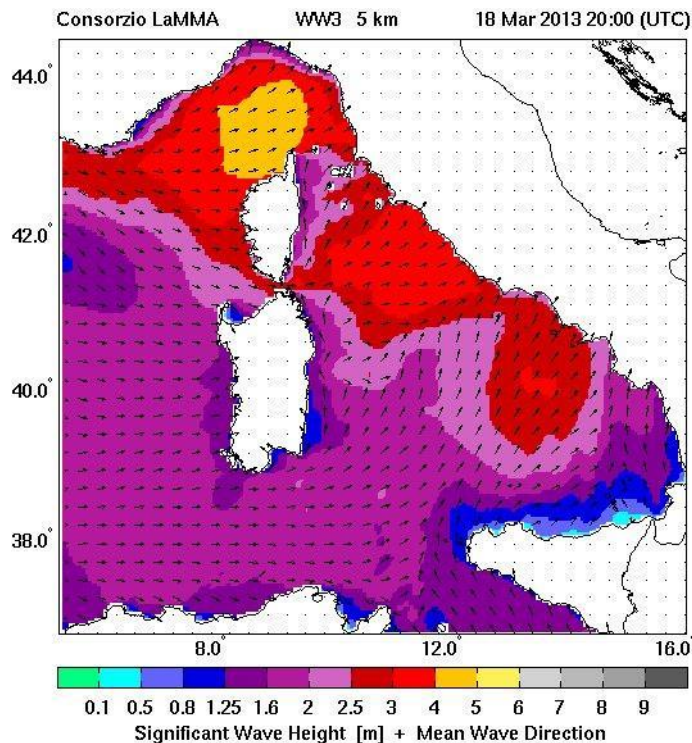

Aim of the discussion

- X-band radar, and the other instruments installed near the Costa Concordia site, give a very local concentration of different kinds of measurements.
- **This system represents a unique small laboratory, and a major source of data, for testing the present forecasting capabilities of wave and current models at such local scales.**
- Here we discuss the evolution of a small pollution event, probably due to the presence of many boats, that occurred during the parbuckling operation.

Operational meteo-marine forecasting chain

The meteorological information for supporting the wreck removal operations is obtained by meteorological and wave forecasting models.

The operational modeling chain include nested atmospheric models based on WRF code, wave forecasting models based on WW3 and SWAN codes, and hydrodynamic models based on ROMS code.

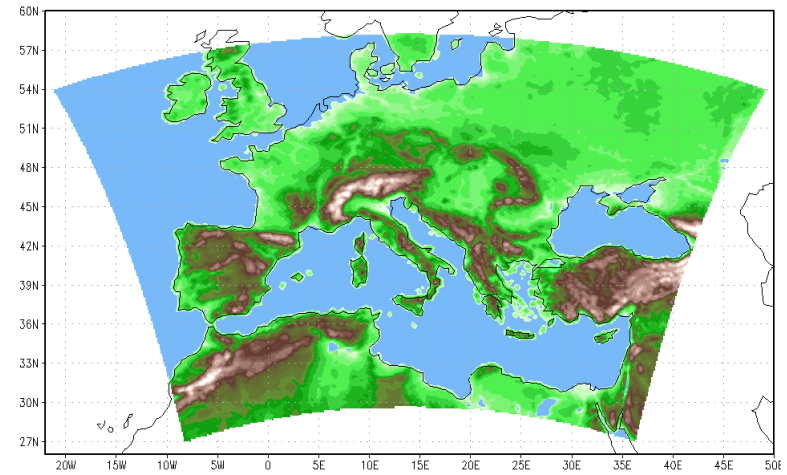

Meteorological models

Consorzio LaMMA ARW 12km - (GFS 50km)

Wave models

WW3 - 12 km

WW3 - 5 km

SWAN - 600 m

SWAN vs Giglio buoy

Significant Wave Height

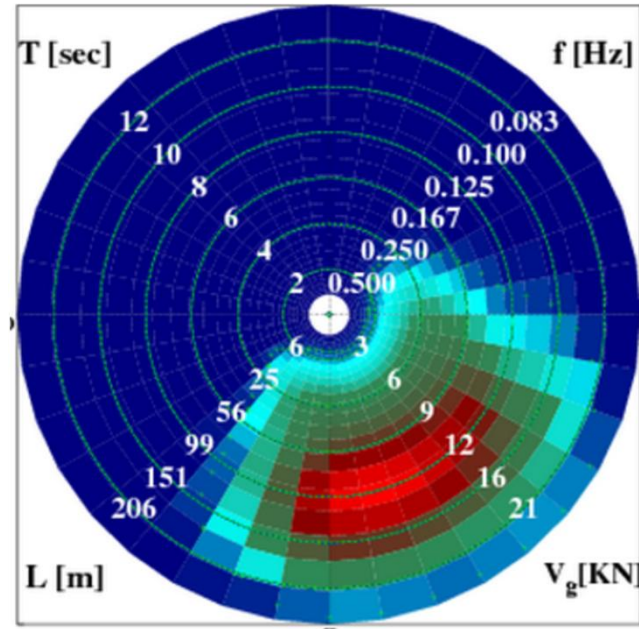

Wave model vs RADAR spectra

RADAR

WW3

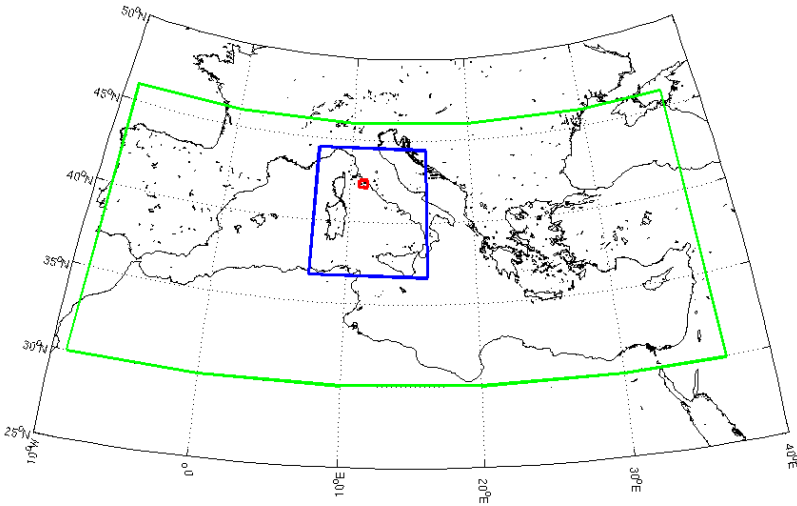

SWAN

- Measured wave spectra are compared with corresponding wave spectra from an operational WW3 model at 5 km resolution and a SWAN model at 600 m resolution.
- In all cases we observe similar spectrum shapes but SWAN shows a better agreement in terms of directions, due to a better capability of the model to describe wave refraction.

Hydrodynamic models

ROMS model configurations:

- TYRRENO ROMS
 - Nested on MFS MyOcean (6 km resolution, daily averaged data)
 - 2 km resolution
 - 30 vertical levels
 - One day spin-up
 - LaMMA-WRF 3 km atmospheric model (nested in ECMWF)
- GYGLIO ROMS
 - Nested on TYRRENO ROMS
 - 400 m resolution
 - 30 vertical levels
